ABSTRACT

The research aimed to discuss the determinant factors of earnings quality and the economic consequences in Indonesian capital market. Those factors are innate, performance, company risk and industry risk. The quality of earnings was measured attributes are accrual quality, persistence, predictability, smoothness, and the quality of factorial earnings, whereas the economic consequence was measured of security residual variance.

The research employed three steps of testing, namely (1) testing of the attributes of earnings quality were different from each other, (2) analyzing the determining factors of earnings quality and (3) testing the effect of earnings quality in the stock market in terms of the relationship between information asymmetric and the earnings quality.

The result of the first testing showed that all of the four attributes of earnings quality were different from each other. The analysis of determinant factors showed that leverage variable had a significant relationship with five attributes of earnings quality, than sales and firm size showed significant relationship with four attributes of earnings information quality. The other variables such as operation cycle, performance and the classification of the industry resulted in two attributes of earnings quality. The economic consequence testing resulted in three attributes of earnings quality that had a significant relationship with the security residual variance. Those attributes were accrual quality, smoothness, and factorial earnings quality.

Key word: earnings quality, innate factors, performance, company risk, industry risk, security residual variance

* This study is a part of my dissertation at Gadjah Mada University. I would like to express my deepest thanks to my promotor Prof. Dr. Bambang Sudibyo, MBA; Prof. Dr. Jogiyanto Hartono, MBA; and Dr. Gudono, MBA.
1. Introduction

So far, the financial statements produced by companies are employing accrual-based accounting due to its relevance to the measurement of company financial performance, (Dechow 1994; Dechow et al. 1998; Palepu et al. 2000; Wild et al. 2001; Dechow and Dichev, 2002, and Liu et al. 2002), its ability to show the real financial condition and to predict the future cash flow (Wild et.al 2001), and its ability to predict the movement of the future stock price (Chan et al. 2001). This is supported by Financial Accounting Standard Board by stating that the *Information about enterprise earnings and its components measured by accrual accounting generally provides a better indication of enterprise performance than does information about current cash receipts and payments* (SFAC No.1 paragraf 44). Moreover, the Financial Accounting Standard also states that earnings information was oftenly used as the measurement of company performance as well as other measurements such as return on investment and something related to earnings per share.

The earnings information resulted from the accrual accounting is closely related to the earnings quality (Thomas and Zhang, 2000; Hribar, 2000; Richardson, 2001; and Dechow dan Dichev, 2002), which are very important for the users of financial statements such as the investor and creditor who use it as the basic of economic decision making especially those related to contracting decision and investment decision. In addition, the financial statement can also be used, indirectly, as one of the quality indicators of financial reporting standard as made by the standard setters.

The perspective of contracting decision, the quality of earnings can be used to make decisions related to corporate governance practices. In addition, it can also be used as the basis determine the company’s salary allocation (Schipper, 2004). The low-quality earnings only causes unexpected transfer of prosperity, for example if the company employed the overstated earnings as the indicators of manager’s performance, overcompensation may happen.

The perspective of investment decision making, it is important for the investors to know the company’s earning quality so as to enable them to reduce the information risk (Schipper, 2004). The investors tend to calculate the information risk by analysing the financial information so that the information does not contain a
major risk of loss. Investors do not expect the low-quality earnings information for it indicates that there is a poor resource allocation. Therefore, it can be concluded that the high-quality information earnings is a sign for reducing the information risk. The investors seek for the minor information risk. This information can be seen from how good the quality of company’s earnings is.

The earnings quality is an important part of financial reports as contained in the obtained company’s earnings. This happens because the investors are going to “buy” the future earnings coming from earnings of the current year reported by the company. The cases of multinational company such as Enron, World Com, and Xerox are the concrete cases related to the problem of earnings quality. The problem is ‘is the quality current earnings good?’ The current earnings is said to be good in quality if the earnings can be used as the reliable indicators for the future earnings (Penman, 2003) or have a strong association with the future operating cash flow (Cohen, 2003). Therefore, the company can make the proper accounting policy so that the obtained earnings is high in quality which results in the sustainable company’s operation..

The researches on earnings quality were conducted using two kinds of approaches (Francis et al. 2004). The first approach is the research related to the factors trigerring the quality earnings and the second approach is how far the user of financial statements respond to the quality of earnings information. The first approach is related to the study of determining factors which result in the earnings quality. The focus of this approach is the internal factors of the company which is related to the inherent or intrinsic factors of the company itself. That is why this factors are called firm specifics or firm characteristics. The second approach is related to external factors as the response of the users of financial information or statements. One of the primary users is the investors. They need the information to reduce information asymmetric. The less the information asymmetric, the more similar the information obtained or accessed by the investors. It implies that the private information can be reduced or even omitted.

The factors determining the earnings quality consist of some influencing factors such as innate factors, past performance, intitution risk, and environmental risk. The economic consequence of earnings quality is the investor reaction in the form of investment decision made by the investors in the stock market. The reaction can be in the form of the reaction between the earnings quality and the information
asymmetric, which in turn will affect the cost of capital of the company (Barone, 2002; Barth and Landsman, 2003; Bhattacharya et al. 2003; Francis et al. 2003a, 2003b; Cohen, 2003; and Aboody et al. 2003). The theory of economics states that, ceteris paribus, increasing the quality of financial information reduces information asymmetries and hence lowers the cost of capital (Diamond and Verrechia, 1991; Glosten and Milgrom, 1985; Amihud and Mendelson, 1986; Easley and O'Hara 2003; and Cohen, 2003).

One of the economic consequences of financial information happened in the stock market is the stock liquidity. (Healy dan Palepu, 2001). The stock liquidity plays a significant roles because it is capable of reducing the information asymmetries between informed investor and uninformed investor. The increasing stock liquidity in the stock market implies the fair price as stated by Diamond dan Verecchia (1991) and also by Kim and Verecchia (1994).

The motivation of the research is trying to study the issues related to the earnings quality of a company focusing on the determinant factors and the economic consequences. The research is also trying to measure the earnings quality using the accounting-based attributes for most researches on earnings quality measurement conducted in Indonesia used market-based attributes such as value relevance and earnings response coefficient. In addition, the research is also trying to offer and study the alternative attribute of earning quality. It was presented as the factor analysis of four attributes of earnings quality which in turn is called factorial earning quality.

2. The Research Problem

Based on the introduction explained previously, the problems of the research were related to what determinant factors influencing the earnings quality of a company and how far/what economic consequences happen in the security market in the form of the effect of market liquidity in that market. To be specific, the research tried to answer the questions as the followings:

1. Do the attributes of accounting-based earnings quality such as accrual quality, persistance, predictability and smoothness represent the earnings quality? Do they differ from each other?
2. What factors are influencing the earnings quality of a company?
3. Is there any association between the earnings quality and the information asymmetry?

4. Do the attributes of earnings quality differ from each other when associating with the information asymmetry?

3. Literature Review and Development of Hypothesis

3.1. Earnings quality, determinant factors and economic consequences

There are some definitions of earnings quality but basically those definitions have two perspectives. The first perspective states that the earnings quality is closely related to the company performance as shown by the obtained earnings in the current year. The earnings quality is considered high if the earnings in the current year can be used as the indicator to predict the future earnings (Penman and Zhang, 2002; Richardson et al. 2001; Beneish and Vargus, 2002; Lev and Thiagarajan, 1993; Mikhail et al. 1999; Richardson, 2003) or strongly associated with the future operating cash flow (Cohen, 2003; Dechow and Dichev, 2002). This perspective shows that the focus of measuring the earnings quality is closely related to the characteristics of the financial statements. The second perspective believes that the earnings quality is closely connected to the performance of company’s stock in the stock market. The stronger the relationship between the earnings and the market returns, the higher the earnings quality (Chan et al. 2001; Lev and Thiagarajan, 1993). Therefore, the earnings quality is the construct that can be analysed using two perspectives. Those are the earnings quality which is related to the cash and the earnings themselves or the earnings quality which is related to the stock return. Those constructs of earnings quality could not be observed directly, instead it can be observed and measured using proxies or attributes contained in the earnings itself.

Tabel 1 presents the summary of attributes of earnings quality employed in this research.
The determinant factors of earnings information are the factors influencing the earnings quality. Those factors consist of innate or intrinsic factors which originally come from the environment where the company operates and the other factors influencing the degree of company discretionary. Those determinant factors varies greatly from one research to another depending on the purpose or the research itself. The following table presents the summary of the results of the previous researches on the determinants factors of earnings quality.

The earnings information resulted from the accrual accounting process will be very useful as long as it is used as the primary sources of information in decision making made by the users of financial statements. The investors as one of the primary user will consider and analyse the information so as to make favorable investment decision. How far the investor response towards the earnings information shows whether or not an investment decision have considered the earnings information as the primary source of information. In the context of the response, there are two primary conditions to be fulfilled to make the information effective as the primary source of information so that it will be usefull for the investors to make decision. The first condition is the information presented is easily accessed and broadly distributed to the investors. The absence of this condition only results in information assymetry. The second condition is the information contains a minor information risk.
The information about the degree of information asymmetry is the private information of informed investors, whereas the other investors (uninformed investor) do not have such information. In other words, there is imbalance in obtaining and possessing information. In this condition, the informed investors has more favorable condition for having such private information. The information asymmetry can cause trade imbalance so that the earnings will be obtained only by certain investors. One way to reduce the information asymmetry is by revealing the qualified information. The research offers the way of revealing qualified information by increasing the company’s earnings quality. Some researches have proven that increasing the earnings quality is capable of reducing the information asymmetry which in turn establishes the market liquidity (Verrechia, 2001; Leuz and Verrechia, 2000; Cohen, 2003).

Diekens (1991) had observed the relationship between the information asymmetry and the equity issues. The purpose of his research is testing the relevance of information asymmetry among the managers and equity market during the process of the announcement of equity issues. There are four proxies of information asymmetry, market reaction on earnings announcement, residual variance of return, amount of publik announcement, and trade intensity. The result of the research is significant relation between information asymmetry and equity issues.

3.2. The Formulation of Hypothesis

The theory behind the research is the theory about valuation or valuation model (Cornel and Landsman, 2003; Christensen et.al, 2005). This model tests the earnings and other accounting information in the current year in order to predict the future earnings. This model had been employed by oleh Dechow (1994), Sloan (1996), Dechow et. al (1998), Dechow and Dichev (2002).

Based on the previous research findings, the hypotheses of this research were formulated as the followings:

H1: There is no difference among the attributes of the company’s earnings quality

H2a: The longer the company operation cycle, the lower the quality of company’s earnings

H2b: The bigger the volatility magnitude of company sale, the lower the quality of company’s earnings
SIMPOSİUM NASİONAL AKUNTANSİ 9 PADANG

H2c: The bigger the company size, the lower the quality of company’s earnings
H2d: The older the company, the higher the quality of company’s earnings
H2e: The low portion of loss positively associated with the high quality of earnings
H2f: The higher the rate of company’s liquidity, the higher the quality of company’s earnings
H2g: The higher the rate of company’s leverage, the higher the quality of company’s earnings
H2h: There is a relationship between the earnings quality and the industry classification risk.

H3a: The level of the earnings quality is associated with the level of information asymmetry.
H3b: There is a difference in relationship between the attributes of earnings quality and the level of information asymmetry.

3. Research Method

3.1. The Data and Sample of the Research

The data employed in this research were totally taken from manufacture companies listed in the Jakarta Stock Exchange. The sampling technique was purposive sampling, focusing on the companies that had been listed in the Jakarta Stock Exchange since 1 January 1998. Therefore, the research employed the secondary data in the form of financial statement of the companies starting from 1998 until 2003.

3.2. Research Variables and The Measurements

The variables employed in this research consist of those related to the determinant factors of earnings quality and its economic consequences. The variables are the operation cycle, sales volatility, company size, company age, performance, liquidity, leverage and classification of industry. The measurement of the determinant factors is presented in table 2.

The earnings quality is unmeasurable construct directly. However, it can be measured by attaching the attributes of the earnings quality to a certain proxy. (Francis et al. 2003b; 2004; Schipper and Vincent, 2003; and Schipper, 2004). The variable of earnings quality in this research was attributed or being proxied based on
the accounting attributes, that is accrual quality, persistence, predictability, smoothness and factorial earnings quality. The underlying concept of accrual quality and smoothness is the same, those are earnings and cash flow. On the other hand, the persistence and predictability involved the information on the comparison between last year and current earnings (autoregressive model).

Accrual quality tries to find out how close the cash flow and the accrual. The further it is results in the bigger distortion of recognise cash. This condition means that the earnings does not reflect the reality (or it can said that the accrual quality is low). On the contrary, the closer it is, the earnings is more powerful in reflecting the reality. The smoothness resulted from the ratio between the earnings deviation standard before the extraordinary accounts per assets devided by the standard deviation of operating cash flow per total assets.

The persistence was measured by observing the value of beta ($\beta_1$) from the autoregresive equation of annual earnings (model AR1). The higher it is, (the more it is close to 1), the higher the resulted coefficient ($\beta_1$) shows the earnings persistance. On the contrary, the smaller the coefficient of beta (the closer it is to zero), the lower the earnings quality or the higher the transitory earnings. The predictability was measured by observing the error of autoregressive equation of the annual earnings (model AR1) using the formula of the square root of the error variance square ($\sqrt{\sigma^2(\gamma_t)}$). The bigger the value of predictability, the less powerful the earnings predicts the future earnings, on the contrary, the smaller the value of predictability, the more powerful the earnings predicts the future earnings. The measurement of every attributes of earnings quality is presented in table 1.

The economic consequence of earnings quality for the investor valuation can be in the form of information asymmetry and equity cost. Information asymmetry underlines the estimation risk or market liquidity which consider the difference of information possesed by informed investors and uninformed investor. Based on the difference, the uninformed investors expect a higher risk premium from a certain portfolio so that there is a balance in the information access. The information difference is expected to be able to increase the quality and the content of financial information so that it can reduce the information asymmetry (Leuz and Verrechia, 2004; Callahan et al. 1997). The research measured the information asymmetry using the residual variance of stock return as the adjusted market of
residual varian of abnormal return on daily stock price in one accounting period (Dierkens, 1991).

3.2. The Empirical Model

The data analysis of this research was conducted in three steps of testing, namely:

1. Testing if there is no overlapping among the accounting attributes as the proxis of earnings quality. If they are different from each other, the further testing is done by analysing four of the attributes to form one new attribute of earnings quality.

2. Conducting a factor analysis on the determinant factors of earnings quality.

3. Testing the effect of earnings quality in the stock market by studying the economic consequence in the stock market in the form of the relationship between the information asymmetry and the company’s earning quality.

The first analysis was conducted by testing the auxiliary regression (Gujarati, 2003), that is a regression which applies one attribute of earnings quality as the dependent variable towards other earnings quality attributes as the independent variable which later on produces the auxiliary $R^2$ (Francis et al. 2003b; 2004).

As for the testing of determinant factors of earnings quality, the research conducted the testing using the regression equation as the followings:

$$ KL_{n,t} = \alpha_0 + \beta_1 \text{operating cycle}_t + \beta_2 \text{sale}_t + \beta_3 \text{size}_t + \beta_4 \text{age}_t + \beta_5 \text{performance} + \beta_6 \text{Liquidity} + \beta_7 \text{Leverage}_t + \beta_8 \text{industry classification}_t + \epsilon_t \ldots $$

(1)

$KL_{n,t}$ consists of:

$KL_{1,t} = $ accrual quality;
$KL_{2,t} = $ persistance;
$KL_{3,t} = $ predictability;
$KL_{4,t} = $ smoothness

$KL_{5,t} = $ factorial earnings quality

The third step of analysis was testing the relationship between the attributes of earnings quality and the information asymmetry using the multivariat regression as the followings:
VR_{1,t} = \alpha_0 + \beta_1 KL_{n,t} + \beta_2 Leverage_t + \beta_3 Beta_t + \beta_4 Size_t + \varepsilon_t . . . . . . (2)

VR_{1,t} = the variance of security residual
KL_{1,t} = accrual quality
KL_{2,t} = persistance
KL_{3,t} = predictability;
KL_{4,t} = smoothness, and
KL_{5,t} = factorial earnings residual

The additional testing in third analysis is the testing the superior model among attributes of earnings quality and information asymmetry. The testing was conducted using Non-Nested model by applying Davidson-MacKinnon J Test or J test (Gujarati, 2003).

4. Result and Discussion
4.1. Testing of Earnings Quality Attributes

The result of auxiliary regression analysis showed that there was no overlapping among the four variables of earnings quality because the result of correlation attributes were less than 0.5 (Francis et al. 2003b, 2004, and Gujarati, 2003). The result of the auxiliary regression is presented in table 4 as the followings:

<table>
<thead>
<tr>
<th></th>
<th>Accrual Quality</th>
<th>Persistance</th>
<th>Predictability</th>
<th>Smoothness</th>
<th>Auxiliary $R^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accrual Quality</td>
<td>1.000</td>
<td>-0.114</td>
<td>0.557</td>
<td>0.506</td>
<td>0.450*</td>
</tr>
<tr>
<td>Persistance</td>
<td>-0.114</td>
<td>1.000</td>
<td>-0.018</td>
<td>-0.100</td>
<td>0.018*</td>
</tr>
<tr>
<td>Predictability</td>
<td>0.557</td>
<td>-0.018</td>
<td>1.000</td>
<td>0.276</td>
<td>0.313*</td>
</tr>
<tr>
<td>Smoothness</td>
<td>0.506</td>
<td>-0.100</td>
<td>0.276</td>
<td>1.000</td>
<td>0.258*</td>
</tr>
</tbody>
</table>

* significance level of 1%
** significance level of 5%
*** significance level of 10%

The results of the testing presents that the accrual quality shows the highest value of auxiliary $R^2$ (0.45), followed by predictability (0.31), smoothness (0.26), and persistance (0.02). This result confirms the research result conducted by Francis et al. (2004) which obtained the highest value of auxiliary $R^2$ of 0.27. However, the attribute of persistance obtained the smallest value of auxiliary $R^2$ of 0.02. Therefore,
it could be concluded that the attribute of persistence is more likely to overlap with the other three attributes of earnings quality since it only had 2% of coverage.

The factor analysis of the four earnings quality attributes resulted in the followings:

Table 4
The factor analysis of the four earnings quality attributes

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Component/Factor 1</td>
<td>0.882</td>
<td>-0.203</td>
<td>0.755</td>
<td>0.731</td>
</tr>
</tbody>
</table>

The four original variables mentioned above formed one factor which is significantly influenced by the attributes of accrual quality (0.882), predictability (0.755) and smoothness (0.731) (see panel C). The attribute of persistence did not have any influence in forming the new factor since the score was too small (-0.203). Intuitively, the formation of the new factor was influenced by the three attributes of earnings quality namely accrual quality, predictability and smoothness. Two of the attributes, accrual quality and smoothness have the same formula focusing on the earnings variability, that is the comparison between the earnings and the operating cash flow.

4.2.2. The Result of Testing the Determinant Factors of Earning Quality

The testing of the determinant factors of earnings quality is Multivariate Regression Analysis. Therefore, a model assumption testing or classical assumption was priorly conducted. This test consisted of the testing of linearity, multicolinearity, heteroskedasticity, autocorrelation, and the testing of the normality of the predicted value of residuals of each model.

The following table presents the result of regression testing of the determinant factors of earnings quality.
Table 6 presented above shows the factor of operation cycle negatively associated with all of the attributes of earnings quality, but only the attribute of persistence and factorial earnings quality which were statistically significant. The coefficient of significant level for the attribute of persistence was -0,141 (1%), and the factorial earnings quality was -0,231 (5%). This result showed that the longer the operation cycle of the company, the lower the quality of earnings, therefore the hypothesis H2a was accepted. This same result were obtained by Dechow and Dichev (2002), Francis et al. (2004), and Gu et al. (2002) showing that the relationship was negative.

The factor of sales volatility varied in its relationship with the other variables. The attributes of accrual quality, smoothness and factorial earnings quality were negatively related which the coefficient of -0,036 (5%), -1,894 (1%), and -0,189 (1%), while the positive relationship were shown by the attribute of predictability with the coefficient of 0,013 (5%). This result showed that the hypothesis H2b stating that greater the magnitude of sales volatility , the lower of earnings quality was accepted. The same result was also found by Dechow and

Dichev (2002), while the statement the greater the sales volatility the higher the earnings quality was firstly stated by Francis et al. (2004). In this research, it is the same as the attribute of predictability.

The factor of company size showed a negative relationship towards the attributes of persistance, predictability, smoothness and factorial earnings quality which the coefficients were subsequently -0.074 (5%), -0.028 (1%), -1.429 (10%), and -0.170 (10%). This result proved the hypothesis $H_{2c}$ stating that the bigger the company the lower the earnings quality. This result also supports the result of the previous researches (Francis et al. 2004; Gu et al. 2002; Cohen 2003).

The factor of company age showed that all attributes of earning quality did not significantly related so that it was too difficult to interpret. It might happen because the measurement of the variable of company age was conducted improperly. The factor of company performance resulted in the positive relationship for accrual quality with the coefficient of 0.055 (5%), and the predictability with the coefficient of 0.095 (1%). The factor of liquidity showed that only the attribute of predictability which had a significant relationship with the coefficient of 0.0002 in the significant level of 10%. Intuitively, the determinant factors of company age and liquidity showed unstable result due to most of the factors were not significant and only a small number of empirical research showed the good results for this testing.

The factor of leverage showed that all of the attributes were significant and had a positive relationship except for persistance. The coefficients obtained were subsequently 0.139 (1%) for accrual quality, 0.062 (1%) predictability, 3.589 (1%) for smoothness, and 0.934 (1%) for factorial earnings quality, while the persistance had the coefficient of -0.087 (1%). This result proved that the higher the level of leverage of a company, the higher the earnings quality. Therefore, the hypothesis $H_{2g}$ was accepted. This result also supports the results of the previous research like the one conducted by Cohen (2003), Gu et al. (2002), and Francis et al. (2004).

The factor of industry classification showed a negative relationship for the attribute of accrual quality and the factorial earnings quality. The coefficient resulted were subsequently -0.056 (1%) for the accrual quality and -0.152 (10%) for the factorial earnings quality. The negative relationship resulted from the determinant factors of industry classification showed a different result from the research done by Gu et al. (2002). Therefore, the hypothesis $H_{2h}$ about the relationship between the
classification industry and the earnings quality was accepted, especially for the attributes of accrual quality and the factorial earnings quality.

4.3. The Results of Testing the Economic Consequence of Earnings Quality

4.3.1. Descriptive Statistics

The following table presents the descriptive statistics of testing the economic consequence of earnings quality.

4.3.2. The Result of Testing the Economic Consequence of Earning Quality

The classic assumption of regression analysis on the economic consequence of earnings quality showed that there was no serious problem except for the attribute of predictability and the factorial earnings quality which underwent heteroskedasticity although it had been solved.

Table 8 below presents the result of testing the economic consequence of earnings quality.
The Economic Consequence of Earnings Quality.

</tbody>
</table>

Notes:
* significant level of 1%
** significant level of 5%
*** significant level of 10%
Vr = security residual variance

The testing of economic consequence among the security residual variance and the attributes of earnings quality showed that only the accrual quality (model 1), smoothness (model 4), and factorial earnings quality (model 5) were significant, while the attribute of persistance (model 2) and predictability (model 3) were not significant. The coefficient resulted from model 1 was 0.039 (1%), model 4 was 0.005 (1%), and model 5 was 0.005 (1%). Therefore, the hypothesis 3a was accepted for the attributes of accrual quality, smoothness and factorial earnings quality.

4.3.3. The Comparison of the Models of Economic Consequence of Earnings Quality

The comparison was conducted using non nested hypothesis testing especially Davidson-MacKinnon J test or J testing (Gujarati, 2003:533). The result of J testing showed that the accrual quality (model 1) was superior to the smoothness (model 4) and factorial earnings quality (model 5). This findings was drawn from the result that the hypothesis stating that model 1 is superior to model 4 and model 5 was accepted. Meanwhile, model 4 and model 5 did not superior to each other since the hypothesis stating so was rejected. Therefore, it can be concluded that the attribute of accrual quality was more superior to the other attributes of earnings quality.
quality such as smoothness and factorial earnings quality in the economic consequence of earnings quality testing.

5. Conclusion, Limitation and Future Research

5.1. Conclusion

The conclusions of the research were presented as the followings:

1. There was a difference among the attributes of earnings quality so that there was no overlapping among the four attributes of earnings quality. This was because the degree of overlap was not more than 0.5. The analysis factor of the four attributes mentioned above resulted in one attribute of earnings quality namely factorial earnings quality. The formation of factorial earnings quality came from three components of attributes namely accrual quality, predictability and smoothness.

2. The result of testing the determinant factors of earnings quality showed that the attribute of accrual quality was influenced by sales volatility, company performance, leverage, and industry classification. The attribute of persistence was influenced by the operation cycle, the company size and leverage. The attribute of predictability was influenced by the sales volatility, company size, company performance, liquidity and leverage. Smoothness was influenced by the sales volatility, company size and leverage. The factorial earnings quality was influenced by the factor of operation cycle, sales volatility, company size, leverage, and industry classification.

3. The result of testing the economic consequence of earnings quality showed that three attributes of earnings quality associated with the economic consequence namely accrual quality, smoothness and factorial earnings quality. Those three models showed that the accrual quality was superior to the smoothness and factorial earnings quality. Meanwhile, the attribute of smoothness and the factorial earnings quality was not superior to each other.

5.2. Limitation and Future Research

The limitations of the research were presented as followings:

1. The period of research sample between 1998 until 2003, where the period was rebuild of economic crisis in Indonesia. The year of observation can be extended for the future research, considering that the period of research was in recovery stage of economic crisis.
2. The sample of the research is manufacturing firms, where many firms in economic crisis to make restructurisation and holding company. Two conditions above not disain in this research. Further research can be developed in this research by involving the variable of holding company matters and the company which conduct restructurization.
